Molecular phylogenetics of *Pimpinella* and allied genera (Apiaceae), with emphasis on Chinese native species, inferred from nrDNA ITS and cpDNA intron sequence data

Zhi-Xin Wang, Stephen R. Downie, Jin-Bo Tan, Chen-Yang Liao, Yan Yu and Xing-Jin He

Z.-X. Wang, J.-B. Tan, Y. Yu and X.-J. He (xjhe@scu.edu.cn), Key Laboratory of Bio-Resources and Eco-Environment of the Ministry of Education, College of Life Sciences, Wangjiang Road no. 29, Sichuan Univ., CN-610064 Chengdu, PR China. – S. R. Downie, Dept of Plant Biology, Univ. of Illinois at Urbana-Champaign, Urbana, IL 61801, USA. – C.-Y. Liao, College of Architecture and Environment, Sichuan Univ., CN-610064 Chengdu, PR China.

The genus *Pimpinella* comprises about 150 species, making it among the largest genera in Apiaceae subfamily Apioideae. It is also a widespread and taxonomically complex group. Previous molecular phylogenetic studies of *Pimpinella* have focused primarily on its Turkish, African and Malagasy congeners, while resolution of relationships among the approximately 44 species of *Pimpinella* native to China remains largely obscure, as is the proper circumscription of the genus. In this study, phylogenetic analyses of nrDNA ITS and cpDNA *rps16* intron and *rpl16* intron sequences were used to assess relationships among *Pimpinella* species and their closest allies, with emphasis on those species of *Pimpinella* native to China, and 54 accessions in the ITS analysis, representing 62 species of *Pimpinella* of which 26 are native to China, and 54 accessions in the cpDNA and combined molecular analyses, the latter representing 20 species of *Pimpinella* native to China. The phylogenies inferred from cpDNA intron sequences are highly consistent with those inferred using ITS data. In all analyses, *Pimpinella* is resolved as non-monophyletic, yet the monophyly of a *Pimpinella* 'core group' in tribe Pimpinelleae is strongly supported. Most Chinese native *Pimpinella* species fall within this core group; the other Chinese species examined appear in four other tribes within the subfamily. For all Chinese taxa, we consider relevant cytological, morphological, palynological, or phytogeographical data supporting their phylogenetic placements. The new combination *Spuriopimpinella arguta* (Diels) X. J. He & Z. X. Wang is proposed.

The genus *Pimpinella* L. comprises about 150 species distributed throughout much of the Old World (Pimenov and Leonov 1993), making it one of the largest genera in Apiaceae subfamily Apioideae. Being the major constituent of tribe Pimpinelleae (Downie et al. 2010), *Pimpinella* consists of mainly perennial herbs possessing cordate-ovoid or oblong-ovoid, slightly laterally compressed fruits constricted at their commissures, each with five filiform ribs (Pu and Watson 2005).

The genus *Pimpinella* was last revised in its entirety by Wolff (1927) who subdivided it into three sections on the basis of petal color, fruit and petal vestiture, and life history. Pu (1985) recognized 39 species of *Pimpinella* native to China and divided them into two sections based on fruit pubescence and conspicuousness of the calyx teeth: *P.* sect. *Tragium* (Spreng.) DC., for those species having pubescent fruit and obsolete calyx teeth, and *P.* sect. *Tragoselinum* (Mill.) DC., for those species having glabrous fruits and obsolete or conspicuous calyx teeth. Several years later, Pu et al. (1992) recognized four additional species of *Pimpinella* from China and, most recently, 44 species of *Pimpinella* were included in the 'Flora of China', but without sectional affiliations (Pu and Watson 2005).

Previous molecular systematic studies of Pimpinella have elucidated its complex taxonomy. Tabanca et al. (2005) examined the phylogenetic relationships among 26 Pimpinella taxa native to Turkey and adjacent areas to assess patterns in the distribution of their essential oils. Their work supported the monophyly of Pimpinella, although they suggested that additional taxonomic sampling from other geographic regions would improve our understanding of relationships and, in turn, secondary metabolite evolution in the genus. Spalik and Downie (2007) demonstrated that the African members of Cryptotaenia DC. and their allies constitute a sister group to Eurasian Pimpinella. With the exclusion of P. betsileensis Sales & Hedge from Madagascar, Pimpinella was maintained as monophyletic. Magee et al. (2010) expanded the study of African and Malagasy Pimpinella species and reported that the genus Pimpinella is rendered paraphyletic by the inclusion of African

Cryptotaenia and the small African and Malagasy endemic genera Frommia H. Wolff and Phellolophium Baker. They also reported that the sectional classification of the genus proposed by Wolff (1927) is largely artificial. Zhou et al. (2008, 2009), in their studies of Chinese Apiaceae subfamily Apioideae, showed that *Pimpinella* was polyphyletic, with P. smithii H. Wolff occurring within tribe Selineae and P. acuminata (Edgew.) C. B. Clarke, P. henryi Diels, and P. purpurea (Franch.) H. Boissieu falling within the east Asia clade of Downie et al. (2010). Pimpinella candolleana Wight & Arn., P. yunnanensis (Franch.) H. Wolff, and P. rockii H. Wolff were the only species of Pimpinella they examined from tribe Pimpinelleae. Additionally, the recent paper by Downie et al. (2010) listed P. brachycarpa Nakai in the Acronema clade, P. heyneana Wall ex Kurz possibly in tribe Echinophoreae, and P. siifolia Leresche in tribe Pyramidoptereae, with only the first of these three species occurring in China. Sium serra (Franch. & Sav.) Kitag., previously referable to Pimpinella, finds affinities with other members of tribe Oenantheae (Spalik and Downie 2006). However, to date, very few species of Pimpinella from China and their putative allies have been included in published molecular phylogenetic studies. The proper generic boundary of Pimpinella, as well as its infrageneric relationships especially among those species native to China, remains unclear, thus further investigation of this large and taxonomically problematic group is necessary.

The nuclear ribosomal DNA (nrDNA) internal transcribed spacer (ITS) region is a popular marker, whose sequences comprise the most comprehensive database for Apiaceae subfamily Apioideae phylogenetic study to date (Downie et al. 2010). Phylogenetic trees derived from these data are generally congruent with those inferred from chloroplast markers (Downie et al. 2000b, 2001). To bolster support for these ITS trees, additional evidence from chloroplast DNA (cpDNA) sequences is typically required, so in this study we also consider sequence data from the rps16 intron and *rpl16* intron regions. Data from these two introns are already available for some Chinese species of Pimpinella and its allies through a previous study (Zhou et al. 2009). The major objective of this study is to assess relationships among Pimpinella species and their closest allies, with emphasis on those species of Pimpinella native to China. We also assess the monophyly of the genus, as previous studies have suggested that it is likely not monophyletic, and further evaluate the traditional sectional classification of native Chinese Pimpinella species erected using morphological characters. Our long-term goal is to produce a modern classification for *Pimpinella* and its allies that reflects its evolutionary history, of which this study of its Chinese congeners represents a small but important contribution.

Material and methods

Taxon sampling

Forty-four species of *Pimpinella* are recognized in the 'Flora of China' (Pu and Watson 2005), with 26 of these included in the present investigation. However, not all 44 species have

distinct boundaries, as a few groups of taxa are morphologically indistinguishable (discussed below) and may not represent good species pending further investigation. We collected 20 species (27 accessions) of native Chinese Pimpinella from the field, as well as material of Melanosciadium pimpinelloideum H. Boissieu, Nothosmyrnium japonicum Miq., and N. xizangense R. H. Shan & T. S. Wang. All vouchers were deposited in the herbarium of Sichuan Univ. (SZ, Table 1). Ninety-two additional accessions of Apiaceae subfamily Apioideae were also included based on sequence data available in GenBank (Table 2); these accessions represent 41 species (44 accessions) of Pimpinella, five of which are native to China. Included here was Spuriopimpinella calycina (Maxim.) Kitag., recognized by Ohwi (1965) in the 'Flora of Japan', but treated as Pimpinella calycina Maxim. in the 'Flora of China' (Pu and Watson, 2005) and herein.

For many of the remaining 18 species of *Pimpinella* native to China, herbarium material is extremely limited, comprising sometimes only the type specimens. When material was available for analysis, it proved too old for successful PCR amplifications and/or DNA sequencing. For some species, plants are no longer growing at the type localities or they exist only in very small populations and were not sampled. Moreover, some taxa appear morphologically indistinguishable from others. As examples, the type specimen of P. helosciadoidea de Boiss. (holotype: P!) is obviously identical to that of *P. smithii* (F. T. Pu et al. 105, topotype; CDBI!) and type material of *P. fargesii* de Boiss. (Henry 6404, 7331, syntype: P!) looks the same as that of P. henryi (Henry 7101, isotype: K!). Pimpinella koreana (Y. Yabe) Nakai has been recognized as a variety of P. nikoensis Y. Yabe (Yabe 1903), which is treated as Spuriopimpinella nikoensis (Yabe) Kitag. in the present investigation. *Pimpinella komarovii* (Kitag.) R. H. Shan & F. T. Pu (previously treated as Spuriopimpinella komarovii) resembles P. arguta Diels and P. brachycarpa morphologically. Pimpinella cnidioides H. Pearson ex H. Wolff was previously treated as a variety of P. thellungiana H. Wolff (Pu and Watson 2005) and can be distinguished from the latter only by the division pattern and size of the leaves. As a result, P. helosciadoidea, P. fargesii, P. koreana, P. komarovii, and P. cnidioides were not considered further in this study. With respect to P. renifolia H. Wolff, P. bisinuata H. Wolff, P. atropurpurea C. Y. Wu ex R. H. Shan & F. T. Pu, and *P. tonkinensis* Chermezon, they are all considerably similar to P. candolleana, according to their descriptions in the 'Flora of China' (Pu and Watson 2005) and our own observations of specimens. Collections of each are also very limited, with P. renifolia and P. atropurpurea existing only as types. We visited the type locality of P. liana Hiroe over two consecutive years but failed to find any plants. The species P. nyingchiensis Z. H. Pan & K. Yao, P. xizangensis R. H. Shan & F. T. Pu, P. filipedicellata S. L. Liou, and P. pimpinellisimulacrum (Farille & S. B. Malla) Farille are distributed in south or southeastern Tibet and exist as very few collections or only type material collected in the 1970-1980's. The situation is similar to the poorly known species P. triternata Diels occurring in Chongqing and to P. silvatica Hand.-Mazz., P. grisea H. Wolff, and P. refracta H. Wolff distributed only in northwest Yunnan. We have strived to sample extensively by examining herbarium Table 1. Plant accessions from which sequences were generated in this study, with corresponding source and voucher information and GenBank numbers. All vouchers were deposited in the herbarium of Sichuan Univ. (SZ).

specimens from multiple herbaria (PE, KUN, CDBI, NAS) and carrying out fieldwork in localities where these scarce plants were previously found. While we have made great efforts to comprehensively sample these native Chinese *Pimpinella* species, material for several is simply not available for study.

In the ITS component of the investigation, 122 accessions (representing 111 species) were considered, 30 of which were newly generated for this study (Table 1). Included here were 62 species of *Pimpinella* of which 26 are native to China. For the cpDNA (*rps16* intron and *rpl16* intron) and combined ITS and cpDNA datasets, 54 accessions representing 20 native Chinese *Pimpinella* species were included, with 29 accessions newly sequenced (Table 1). The emphasis of our samplings focused on the native Chinese *Pimpinella* species plus their closest congeners, the latter chosen through results of several previous phylogenetic studies (Zhou et al. 2008, 2009, Downie et al. 2010, Magee et al. 2010) and our own preliminary investigations.

We rooted all trees with *Physospermopsis delavayi* and *Pleurospermum franchetianum* (both tribe Pleurospermeae), based on the results of previous investigations of Chinese Apiaceae subfamily Apioideae (Zhou et al. 2009) and our preliminary analyses of ITS data from a larger set of Apioideae taxa. The names of the major clades identified in the phylogenetic trees are those of Downie et al. (2010).

Molecular methods

DNA was extracted from silica gel-dried leaves collected in the field using the modified method of Doyle and Doyle (1987). The primers ITS4 (5'-TCC TCC GCT TAT TGA TAT GC-3') and ITS5 (5'-GGA AGT AAA AGT CGT AAC AAG G-3'; White et al. 1990) were used for polymerase chain reaction (PCR) amplification of the complete ITS region. Primers rps16 5'exon (5'-AAA CGA TGT GGN AGN AAR CA-3') and rps16 3'exon (5'-CCT GTA GGY TGN GCN CCY TT-3'; Downie and Katz-Downie 1999) were used for amplifying the cpDNA rps16 intron. The cpDNA rpl16 intron was amplified using primers F71 (5'-GCT ATG CTT AGT GTG TGA CTC GTT G-3') and R1516 (5'-CCC TTC ATT CTT CCT CTA TGT TG-3'; Jordan et al. 1996, Kelchner and Clark 1997). The amplification of the ITS region was obtained by initial denaturation for 4 min at 94°C, followed by 30 cycles of 45s at 94°C, 45s at 54°C, and 60s at 72°C, then final elongation of 10 min at 72°C, whereas amplification of both cpDNA intron regions was obtained by initial denaturation for 4 min at 94°C, followed by 36 cycles of 45s at 94°C, 70s at 54°C, and 90s at 72°C, then final elongation of 10 min at 72°C. All PCR products were separated using a 1.0% (w/v) agarose TAE gel and purified using the Wizard PCR preps DNA Purification System following the manufacturer's

Table 2. (Continued).

instructions. The purified PCR products were sequenced in an ABI 310 Genetic Analyzer in both directions using the PCR primers. Primers R1516 and intron3 (5'-TCT GAT TTC TAC AAY GGA GC-3'; Downie et al. 2000b) were used as additional sequencing primers for the *rpl16* intron.

Phylogenetic analyses

DNA sequences were initially aligned using the default pairwise and multiple alignment parameters in Clustal X (Jeanmougin et al. 1998) and subsequently adjusted manually as necessary using MEGA5 (Tamura et al. 2011). All data matrices are available in TreeBase (submission no. S14358). Phylogenetic analyses of the four data matrices (i.e. large ITS, reduced ITS, cpDNA [*rps16* intron plus *rpl16* intron], and combined [reduced ITS and cpDNA]) were carried out using Bayesian inference (BI) and maximum parsimony (MP) methods, implemented using MrBayes ver. 3.1.2 (Ronquist and Huelsenbeck 2003) and PAUP* ver. 4.0b10 (Swofford 2003).

Prior to each BI analysis, a substitution model was selected using the program MrModeltest ver. 2.2 (Nylander 2004) and the Akaike Information Criterion (Akaike 1974, Posada and Buckley 2004). For the large ITS data matrix, the GTR + I + G model was chosen as the best fit. Two simultaneous runs of 5 million generations were performed, each with four Monte Carlo Markov chains initiated and a sampling frequency of 100 generations. The first 10000 trees were discarded (as 'burn-in') before stationarity was reached, prior to determining the posterior probability (PP) values from the remaining trees. BI analyses of the reduced ITS, *rps16* intron plus *rpl16* intron, and combined (reduced ITS and cpDNA) datasets were carried out similarly, using the SYM + I + G, GTR + I + G, and GTR + I + G models for each of these datasets, respectively.

For each data matrix, MP analysis was carried out with gaps treated as missing data, characters unordered, and all character transformations equally weighted. Heuristic searches were performed with 1000 random addition sequence replicates. One tree was saved at each step during stepwise addition, and tree–bisection–reconnection (TBR) was used to swap branches; the maximum number of trees was set to 20000. Bootstrap values were calculated from 1000000 replicate analyses using 'fast' stepwise-addition of taxa and only those values compatible with the majorityrule consensus tree were recorded.

Cytological analyses

Chromosome numbers of two endemic Chinese *Pimpinella* species, *P. caudata* (Franch.) H. Wolff (voucher specimen no. wzx2010090304; SZ) and *P. rhomboidea* Diels (voucher specimen no. T2011082701; SZ) were obtained. Root tips were collected in the morning and then pretreated in a saturated solution of *p*-dichloro-benzene for 3-4 h at room temperature. Subsequently, they were fixed in Carnoy's solution (3:1, ethanol: acetic acid) for 24-36 h and then stored in 70% ethanol at 4°C. The root tips were macerated in a mixture of 1N HCl for 5-10 min at 60° C, stained in 1% carbolic acid Fuchsin for 10 min, and then squashed on

a glass slide. At least five individuals per species were sampled, and the chromosomes of at least 30 metaphase plates from each individual were counted. Known chromosome numbers for 35 additional taxa of *Pimpinella* species and its allies were obtained from literature (Table 3).

Results

Among the 122 ITS sequences examined, the complete ITS region varied in length from 586 to 610 bp. Of the 645 initial alignment positions, 65 positions were excluded from subsequent analyses because of alignment ambiguity. Of the remaining 580 positions, 429 were potentially parsimony informative, 80 were constant, and 71 were autapomorphic. In direct pairwise comparisons of all unambiguous positions across ingroup accessions, sequence divergence values ranged from identity to 26.9% of nucleotides. Sequence characteristics of the other three data matrices (reduced ITS, cpDNA [*rps16* plus *rpl16* introns], and combined [reduced ITS and cpDNA]) are presented in Table 4, as are the tree statistics resulting from MP analysis of each of the four datasets.

The majority-rule consensus tree derived from BI analysis of the large ITS dataset was highly consistent with the MP strict consensus tree derived from these same data. Thus, only the BI tree is shown, with bootstrap support values obtained from the MP analysis presented for those clades resolved in both analyses (Fig. 1). Six major ingroup clades were recovered, with varying degrees of branch support. These clades correspond to the previously designated tribes Pimpinelleae (PP = 1.00, BS = 85%), Selineae (PP = 1.00, BS = 99%), Oenantheae (PP = 1.00, BS = 100%), and Komarovieae (PP = 1.00, BS = 72%), and the Acronema (PP = 1.00, BS = 97%) and east Asia (PP = 1.00, BS = 81%)clades of Downie et al. (2010). Tribe Pimpinelleae contains 75 accessions representing 50 species of Pimpinella, two Chinese Trachyspermum species, four African and Malagasy taxa (Cryptotaenia africana, C. calycina, Frommia ceratophylloides and Phellolophium madagascariense), and twelve other members (Aphanopleura trachysperma, A. capillifolia, Arafoe aromatica, Athamanta macedonica, Demavendia pastinacifolia, Haussknechtia elymaitica, Nothosmyrinum xizangense, N. japonicum, Opsicarpium insignis, Psammogeton biternatum, P. canescens and Zeravschania regeliana). Within tribe Pimpinelleae, we identify three additional major clades collectively comprising the *Pimpinella* 'core group' (PP = 1.00, BS = 93%): (I) eight species of Pimpinella of African distribution; (II) thirteen species (16 accessions) of Pimpinella and two species of Trachyspermum of primarily Chinese distribution (native Chinese species of Pimpinella are boldfaced in all tree figures); and (III) twenty-one species (25 accessions) of Pimpinella and Opsicarpium insignis of Chinese and Eurasian distribution. Considering the placement of other Pimpinella species falling outside of the Pimpinella 'core group', P. brachystyla, P. valleculosa K. T. Fu, and P. smithii occurred in tribe Selineae, P. arguta and P. brachycarpa clustered with P. calycina and Spuriopimpinella nikoensis in the Acronema clade, P. serra Franch. & Sav. was sister group to Sium serra in

tribe Oenantheae, and *P. henryi*, *P. rhomboidea*, *P. caudata*, *P. acuminata* and *P. purpurea* occurred in the east Asia clade.

The BI trees resulting from analyses of the reduced ITS and cpDNA data matrices are presented in Fig. 2. These

trees were generally topologically consistent with those inferred using MP, therefore both PP and BS support values are presented for clades resolved in both analyses. Both ITS and cpDNA data matrices yielded similar numbers of

Table 4. Sequence characteristics and tree statistics for each of the four datasets considered in the study.

*ITS sequences of Acronema paniculatum, Aphanopleura trachysperma, Demavendia pastinacifolia, Halosciastrum melanotilingia, Opsicarpium insignis, Psammogeton biternatum, Psammogeton canescens and Zeravschania regaliana, and the rpl16 intron sequence of Sinolimprichtia alpina were excluded in the statistics of length variation and sequence divergence due to their incompleteness. parsimony informative positions and sequence divergence estimates, although MP analysis of the former resulted in far fewer MP trees than the latter (Table 4). Topological conflicts between the ITS and cpDNA trees were not apparent with regard to the major clades derived, although there were some areas of discordance for interior tree topologies (discussed below). Phylogenetic analyses of the combined dataset (reduced ITS plus cpDNA) yielded a similar phylogenetic estimate to those of the partitioned analyses, especially with regard to relationships of the native Chinese Pimpinella species (Fig. 3). The classification of Pimpinella into two sections on the basis of fruit pubescence and conspicuousness of the calyx teeth does not hold up in light of the molecular phylogenetic results. Members of sections Tragoselinum and Tragium are scattered throughout the Pimpinella 'core group', and because Chinese Pimpinella occurs in other major clades as well, this mixing continues throughout the entire tree (Fig. 3). As such, the traditional sectional classification of Pimpinella is confirmed as highly artificial.

With respect to the cytological analyses, both *Pimpinella* rhomboidea and *P. caudata* have chromosome numbers of

2n = 22 (Fig. 4). The distribution of available chromosome base numbers for *Pimpinella* species and their allies is indicated in Fig. 1. In the *Pimpinella* 'core group', x = 9 is a common chromosome base number, although x = 8 and x = 10 are found here too. For those *Pimpinella* species falling outside of the *Pimpinella* 'core group', a chromosome base number of x = 11 is most remarkable.

Discussion

Discordance between ITS and combined cpDNA intron phylogenies

Few major topological conflicts among the major clades inferred through partitioned analyses were apparent. *Nothosmyrnium* presents one such conflict: either sister group to the *Pimpinella* 'core group' (ITS; Fig. 2a) or falling alongside members of tribe Selineae (cpDNA; Fig. 2b). The unstable relationship of *Nothosmyrnium japonicum* with tribes Pimpinelleae and Selineae was observed previously (Zhou et al. 2009), and resolution of the proper

Figure 1. Bayesian majority-rule consensus tree derived from the large ITS dataset, with corresponding base chromosome numbers presented on the tree for those taxa in which they are available. Posterior probability and MP bootstrap support (\geq 50%) values are shown on branches. Native Chinese *Pimpinella* species are boldfaced. The major clades inferred are discussed in the text.

Figure 1. (Continued).

phylogenetic placement of this small genus may only be achieved through further study incorporating greater sampling at the base of tribe Pimpinelleae and within tribe Selineae. Another conflict is the positioning of tribe Komarovieae, either as sister group to the east Asia clade (ITS) or embedded within the east Asia clade (cpDNA); this conflicting position, however, is not well supported in any tree. Minimal discordance was also apparent in the Chinese Pimpinella group, such as the positioning of one accession of Pimpinella flaccida C. B. Clarke. We attribute this discordance to hybridization and/or incomplete lineage sorting, although polyploidy is unusual for Pimpinella species and we have no record of it having taken place with respect to its Chinese congeners. Moreover, we have never observed apparent interspecific hybrids in the field on the basis of intermediate morphologies. Therefore, incomplete lineage sorting might be a better explanation for the minor incongruence seen between the ITS and cpDNA phylogenies for *P. flaccida*.

Trachyspermum and Opsicarpium

Two Chinese endemic species of *Trachyspermum* (*T. scaberulum* and *T. triradiatum*) fell into the *Pimpinella* 'core group', a result in accordance with studies by Zhou et al. (2008, 2009) where these same two species allied with Chinese native *Pimpinella* in tribe Pimpinelleae. These two *Trachyspermum* species are distantly related to the generic type, *T. ammi*, which occurs in the closely related tribe Pyramidoptereae (Downie et al. 2010). *Trachyspermum* comprises about 12 species, with four of them occurring in China, and it has long been confused with *Pimpinella* (Sheh and Watson 2005). The inclusion of all Chinese *Trachyspermum* species in a subsequent study, as well as a

(a) ITS tree

Figure 2. Bayesian majority-rule consensus trees derived from (a) reduced ITS and (b) cpDNA datasets, each comprising 54 accessions of Apioideae. Posterior probability and MP bootstrap support (\geq 50%) values are shown on branches. Native Chinese *Pimpinella* species are boldfaced.

thorough review of their morphology, is necessary before we can properly assess the relationship between *Trachyspermum* and *Pimpinella*, although it does appear that the two species of Chinese *Trachyspermum* included herein should best be treated as members of *Pimpinella*. Similarly, the Iranian endemic species *Opsicarpium insignis* also falls within the *Pimpinella* 'core group'. Previously, Valiejo-Roman et al. (2006b) reported that *Pimpinella* and *Opsicarpium* are close genera based on molecular data, a relationship supported by their similar fruit structure and pinnate leaves. Our results corroborate the inclusion of *Opsicarpium* into *Pimpinella*.

The heterogeneous nature of Pimpinella

One major outcome of this study is the confirmation that the genus *Pimpinella* is not monophyletic, a result consistent with previous molecular phylogenetic studies of the group, albeit with fewer samples (Zhou et al. 2008, 2009, Magee

Figure 3. Bayesian majority-rule consensus trees derived from analysis of the combined (reduced ITS and *rps16* intron plus *rpl16* intron) dataset. Posterior probability and MP bootstrap support (\geq 50%) values are shown on branches. Native Chinese *Pimpinella* species are boldfaced. Asterisks indicate the Chinese *Pimpinella* taxa classified traditionally in sect. *Tragium*. Solid circles indicate the Chinese *Pimpinella* species classified traditionally in sect. *Tragoselinum*.

et al. 2010). Simply, *Pimpinella* is rendered paraphyletic, with African *Cryptotaenia*, *Frommia*, and *Phellolophium* (as well as two Chinese *Trachyspermum* species and *Opsicarpium insignis*) arising from within it. The results of our study of native Chinese *Pimpinella* also coincide, in part, with traditional treatments based on morphological characters (Pu 1985). While some Chinese native species of *Pimpinella* are closely related to the type *P. saxifraga*, others are not. We

propose a *Pimpinella* 'core group', with the aim to accommodate a monophyletic group of *Pimpinella* species and to highlight those native Chinese members of *Pimpinella* and others that fall outside of this group.

Traditionally, *Pimpinella* has been classified into two groups, sects. *Tragoselinum* and *Tragium*, primarily on the basis of whether their fruits are glabrous or not. These sectional affiliations, however, are not consistently used (Pu and

Figure 4. Mitotic metaphase plates of (a) *Pimpinella rhomboidea* (voucher specimen no. T2011082701, SZ) and (b) *P. caudata* (voucher specimen no. wzx2010090304, SZ).

Watson 2005). The native Chinese species P. acuminata, P. arguta, P. brachycarpa, P. caudata, P. henryi, P. purpurea, P. rhomboidea, P. serra and P. valleculosa are classified in section Tragoselinum on the basis of morphological data, although in the cladograms presented herein they all fall outside of tribe Pimpinelleae in four major clades (Fig. 3). Members of section Tragium are restricted to the Pimpinella 'core group', with the exception of *P. smithii* that occurs in tribe Selineae. Previously, Zhou et al. (2008, 2009) reported the inclusion of *P. smithii* in tribe Selineae and *P. purpurea* in the east Asia clade. Molecular data clearly support the heterogeneous nature of the traditional classification of Pimpinella and the rejection of the recognition of two sections on the basis of fruit pubescence. Characters of fruit morphology and anatomy have long been used in the classification of the family Apiaceae at all hierarchical levels, yet numerous phylogenetic studies (Downie and Katz-Downie 1996, Downie et al. 1998, 2000b, 2001, 2010, Plunkett and Downie 1999) have revealed the highly homoplastic nature of many of these characters, so it is not surprising that we can reject the sectional classification of *Pimpinella* and why others, such as Pu and Watson (2005), have not used it.

Species of Pimpinella falling outside of the 'core group'

Pimpinella serra was first described by Franchet and Savatier in 1879. The combination Sium serra (Franch. & Sav.) Kitag. was proposed in 1941, although the species was retained in the genus *Pimpinella* by some floras (Pu 1985, Pu and Watson 2005). Phylogenetic analysis of cpDNA and ITS sequences (Spalik and Downie 2006, Spalik et al. 2009) revealed that this taxon is allied with members of Sium in tribe Oenantheae and the results presented herein confirm this placement based on new material obtained from Anhui Province of eastern China (Table 1). Pimpinella serra shares the following features with Sium: 1) a preference for moist to wet habitats, 2) fusiform roots, 3) glabrous leaves and stems, 4) stems rooting at the basal nodes, and 5) pinnate leaves with primary divisions that are usually scarcely divided (Pu 1985, Pu and Watson 2005). Thus, like Spalik and Downie (2006), we support the taxonomic placement of this species in the genus *Sium* and its continued recognition as *Sium serra*.

The name Spuriopimpinella was used initially for a group of species within *Pimpinella* (Boissieu 1906) and later, for a new genus (Kitagawa 1941). Its type, S. calycina, was described originally as a species of Pimpinella (Maximowicz 1873). Therefore, it was not fully unexpected that P. arguta and P. brachycarpa fell distantly from the Pimpinella 'core group', allying with Spuriopimpinella calycina (P. calycina) and S. nikoensis in the Acronema clade. The most frequent chromosome numbers in *Pimpinella* are 2n = 18 and 20, while *Spuriopimpinella* species are usually 2n = 22 (Pimenov et al. 2003). Chromosome base numbers of P. arguta, P. brachycarpa (syn. Spuriopimpinella brachycarpa; Pu and Watson 2005), S. calycina, and S. nikoensis are all x = 11(Arano and Saito 1977, Byung-Yun et al. 1996, Li and Li 2005, Pu et al. 2006). Eurasian Pimpinella, on the other hand, has a chromosome base number of x = 9 or x = 10(Magee et al. 2010). Pimpinella arguta and P. brachycarpa, like species of Spuriopimpinella, are all rather slender perennials bearing few, loosely arranged leaves. All four species possess few or solitary umbels, prominent calyx teeth, and ovoid or ellipsoidal, glabrous, laterally compressed fruits. Their carpels are nearly orbicular in cross section, with occasionally only a single carpel maturing (Ohwi 1965, Pu 1985, Pu and Watson 2005). Downie et al. (2010) supported a monophyletic genus Spuriopimpinella in the Acronema clade. Given that Spuriopimpinella is retained in the 'Flora of Japan' as a distinct genus (Ohwi 1965), the morphological and cytological similarities among Spuriopimpinella, P. arguta, and P. brachycarpa, and the molecular evidence presented herein, we support the restoration of Spuriopimpinella brachycarpa (Komarov) Kitag. (Kitagawa 1941), and propose the following new combination:

Spuriopimpinella arguta (Diels) X. J. He & Z. X. Wang comb. nov.

Basionym: *Pimpinella arguta* Diels in Bot. Jahrb. Syst. 29 (1900, p. 496).

Type: China, Chongqing, Wushan, A. Henry 7086 (isotype: P!).

Description

Plants perennial, 40–100 cm, glabrous. Roots fusiform. Stems 2–3-branched. Basal petioles 6–10 cm; blade 2–3-ternate; ultimate segments ovate-lanceolate or rhombic, $2-6 \times 1-2$ cm, with margins sharply serrate and apex acuminate or caudate. Cauline leaves similar to basal, 2-ternate or 3-lobed. Umbels 1.5–4.0 cm across; bracts (0–)2–6, linear, ca 2 mm; rays 9–20, 2–7 cm, very unequal; bracteoles 3–8, linear-filiform, ca 1 mm, shorter than pedicels; umbellules 5–8 mm across, 10–25-flowered, polygamous; pedicels 2–3 mm, elongating to 7 mm in fruit. Calyx teeth conspicuous, lanceolate, ca 0.5 mm. Petals white, obovate, their apex with incurved lobule. Stylopodium conic; styles $2-3 \times$ stylopodium, reflexed. Fruit ovoid, ca 4×3 mm, its surface glabrous; vittae 3 in each furrow, 4 on commissure. Seed face plane.

Distribution and habitat

Spuriopimpinella arguta is endemic to China, and distributed in Gansu, Guizhou, Hebei, Henan, Hubei, Shaanxi, and Sichuan. It grows in coniferous forests, grassland, and scrub at forest margins, 1300–3400 m a.s.l. Flowering occurs from June to August, and fruiting from August to October. A list of specimens observed will be provided upon request.

Similar species

Pimpinella valleculosa and P. smithii are both endemic to China, the former occurring in the Qinling and Daba Mountains extending eastward and the latter being more widely distributed, extending from the east Qinghai-Tibetan Plateau eastward through the Qinling Mountains and then northeastward into northern China. Both species have independent origins from those Chinese native Pimpinella species within the Pimpinella 'core group', the latter distributed primarily in the Hengduan Mountains of southwestern China. The closest relatives to P. valleculosa are currently unknown with the data at hand, although unpublished ITS phylogenies suggest an affinity to several species of Seseli L. (S. Downie et al. unpubl.). Previous studies by Zhou et al. (2008, 2009) supported the position of P. smithii in tribe Selineae and placed it within, or close to, the genus Angelica; Downie et al. (2010) confirmed that P. smithii should be treated as a species of Angelica, as should Melanosciadium pimpinelloideum. Pimpinella smithii is similar morphologically to P. brachystyla (Pu 1985) and their putative close relationship is reflected in the ITS results where P. brachystyla arises from within P. smithii - these results suggest further that P. brachystyla should also be treated within Angelica. Whether these two taxa best represent a single species, or if interspecific hybridization or lineage sorting has confounded understanding of relationships, must be addressed in further studies.

Five species of *Pimpinella* native to China fall within the east Asia clade. A chromosome base number of x = 11 for *P. rhomboidea* (Fig. 4a) is distinct from the members of the *Pimpinella* 'core group', the latter usually possessing a chromosome base number of x = 9. *Pimpinella henryi* is distinguished from those species of the *Pimpinella* 'core group', with its polygamous umbellules, petals not inflexed and with a mucronate apex, and a compressed, round crosssection of the carpel with a slightly concave seed face. In all

trees, *P. caudata*, *P. purpurea*, and *P. acuminata* comprise a well-supported monophyletic group. *Pimpinella caudata* also presents a chromosome base number of x = 11 (Fig. 4b), whereas x = 10 was reported for *P. acuminata* (Cauwet-Marc 1982). Neither of these numbers is prevalent within the *Pimpinella* 'core group'. *Pimpinella purpurea* can be further distinguished from its Chinese congeners in the *Pimpinella* 'core group' by several distinctive morphological features, such as its conspicuous linear-lanceolate calyx teeth and a compressed, round cross-section of the carpel with a slightly concave seed face. Obviously, more work needs to be done in establishing relationships within the east Asia clade, a group circumscribed initially by Calviño et al. (2006), before we can speculate on the phylogenetic affinities of these enigmatic *Pimpinella* species.

Chinese *Pimpinella* congeners within the *Pimpinella* 'core group'

Most Pimpinella species investigated herein allied with the nomenclatural type *P. saxifraga* in the *Pimpinella* 'core group' of tribe Pimpinelleae. Clade II (Fig. 1) contains 11 Pimpinella species native to China. These species share similar ITS sequences (pairwise sequence divergence estimates ranged from identity to 4.3%), a chromosome base number of x = 9 for many species, and the following suite of morphological features: obsolete calyx teeth, ovoid or obovate petals with cuneate bases and apices with incurved lobules, cordate-ovoid fruit with usually a shortly papillosepubescent or hairy surface (or sometimes glabrous), filiform fruit ribs having a pentagonal or nearly circular cross-section of the carpel, and seeds usually adnate to the pericarp (Pu 1985, Pu and Watson 2005). Characters differentiating these species are few and their great similarity may be explained by their short evolutionary history and/or their narrow distribution in southwestern China. Of the 16 Chinese native Pimpinella species studied palynologically (Wang et al. 2012), nine species (P. candolleana, P. chungdienensis C. Y. Wu, P. coriacea H. Boissieu, P. diversifolia DC., P. flaccida, P. kingdon-wardii H. Wolff, P. rockii, P. thellungiana and P. yunnanensis) occur within the Pimpinella 'core group' and all have a uniform subrectangular or equatorially constricted pollen type. The grains are all tricolporate and fall in a similar size category characterized by a polar length between 22.5 and 30.9 μ m, with a P (polar) to E (equatorial) ratio of 1.8 to 2.3. Pimpinella candolleana and its allies are usually perennial plants, having cordate-ovate simple leaves (rarely ternate or pinnate). In contrast, P. flaccida and P. rubescens (Franch.) H. Wolff ex Hand.-Mazz. are both annual plants. They are similar to P. chungdienensis in that they are slenderer and bear only pinnate or small, cordate-rounded simple leaves.

Native Chinese species *P. anisum, P. puberula,* and *P. thellungiana* occur within clade III (Fig. 1) and show a close affinity to a large number of Eurasian species. *Pimpinella anisum* is known only in cultivation (Xinjiang). *Pimpinella puberula* is a wide-ranging species of west and central Asia, with a restricted distribution in Xinjiang (Pu and Watson 2005), and *P. thellungiana* occurs in north and northeast China. *Pimpinella thellungiana* shares many foliage features with *P. saxifraga* (Shishkin 1950, Pu and Watson

2005): radical leaves with long petioles and 3–5 pairs of primary leaflets with ovate blades.

Small, rather featureless fruits generally characterize Pimpinella species. These, compounded with the fact that the fruits don't stay on the plant for long when they mature, make the plants difficult to identify. Furthermore, in herbaria, numerous specimens possess only flowers. Nevertheless, many of the native Chinese species restricted to clade II of the Pimpinella 'core group' do share certain features, such as hairy or papillose, small, cordate-ovoid fruits. Some members of this clade, however, such as P. rubescens and P. flaccida, have cordate-ovoid but glabrous fruits, but they differ from their congeners in the clade by bearing fewer rays (2-3) and flowers (2-4) per umbellule. The Taiwanese endemic species P. niitakayamensis, while also bearing similarly shaped and glabrous fruits, has 6-12 rays and 6-8 flowers per umbellule (Pu and Watson 2005). In a word, members of the Pimpinella 'core group' clade II are usually characterized by 'unsmooth' fruits, an observation that could be further tested as material from additional species not examined herein becomes available for analysis. Pimpinella thellungiana, native to north China, has oblong-ovoid and glabrous fruits similar to those of *P. saxifraga* in clade III. These results are interesting for they suggest that the Chinese native species of Pimpinella restricted to clade II might be distinguishable on the basis of fruit morphology.

Biogeography

The biogeographical history of the *Pimpinella* 'core group', with emphasis on those species native to China, will be treated in a separate publication once sampling has been increased for the genus as a whole and its precise circumscription has been resolved through continued molecular systematic studies of Eurasian Apiaceae subfamily Apioideae. The species considered herein are currently distributed in the east Himalayan region, especially in the Hengduan Mountains and, considering their close affinity to their western and central Asian congeners, likely were derived from an eastward migration of their recent Mediterranean ancestors and subsequent radiation in their present locations. A similar scenario has been invoked to explain the origin and subsequent distribution of another umbellifer, Bupleurum, in southwest China (Wang 2011). In addition, the presence of Chinese native species in clades II and III suggest that the dispersal of *Pimpinella* to China happened more than once, and likely in different time periods, as also exhibited by Bupleurum (Wang 2011). Further speculation on the group's biogeographical history must await additional study.
